

How to adjust the load of wind turbine generator

How do you control a wind turbine?

You can control a turbine by controlling the generator speed, blade angle adjustment, and rotation of the entire wind turbine. Blade angle adjustment and turbine rotation are also known as pitch and yaw control, respectively. A visual representation of pitch and yaw adjustment is shown in Figures 5 and 6. Figure 5: Pitch adjustment.

How is a wind turbine controlled in a high wind speed region?

In the high wind speed region, the wind turbine is controlled to maintain the aerodynamic power produced by the wind turbine. Two methods to adjust the aerodynamic power were investigated: pitch control and generator load control, both of which are employed to control the operation of the wind turbine.

How does a wind turbine control aerodynamic power?

The wind turbine has a pitchable blade to control the aerodynamic power. The dashed line indicates that the pitch angle can be controlled. It is shown that there is a mechanical component (such as a gearbox) between the high-speed shaft and the low-speed shaft. The low-speed shaft is driven by the turbine blades, which generates aerodynamic power.

How a wind turbine is operated in a lower wind speed?

In the lower wind speed, when the aerodynamic power produced by the wind turbine is below the maximum power rating of the power converter, the wind turbine is operated in the C_{Pmax} . The pitch angle of the wind turbine is controlled to have the As the rpm maximum possible C_{Pmax} . changes, the pitch angle is kept at its optimum pitch angle.

How do you calculate mechanical power from a wind turbine?

The mechanical power extracted from the wind is determined by the efficiency of the conversion of the wind energy into the kinetic energy of the blades, and is given by (6) $P_{mech} = C_p(\beta) P_{wind}$, where β is the blade pitch angle, and $C_p(\beta)$ is the power coefficient of the turbine.

How do you control the pitch of a wind turbine?

Two methods of pitch control. By stalling a wind turbine, you increase the angle of attack, which causes the flat side of the blade to face further into the wind. Furling decreases the angle of attack, causing the edge of the blade
